

Physical Properties of Ionic & Covalent Compounds

Potassium Chloride Ionic Compound
 KCl

Solubility

+88°
80°

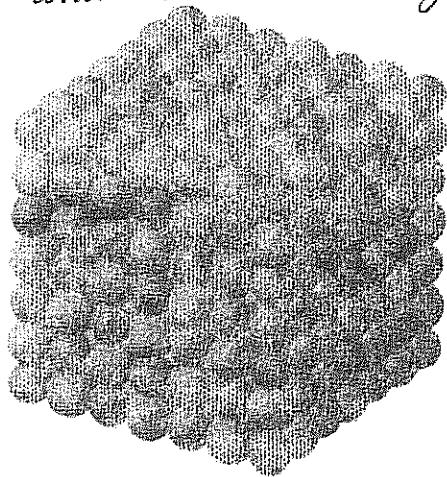

Strong forces between cations & anions hold the ionic crystal together.

Giving the substance enough heat to break the strong attraction between ions is difficult. Lots of energy is needed

Therefore, ionic compounds have

↑ high melting pt.
↑ high boiling pt.

Charges on polar molecules (like water) attract to ions in ionic compounds and dissolve them by pulling the crystal apart. The many small forces of water are enough to break the strong ionic bond.

Soluble in polar substances

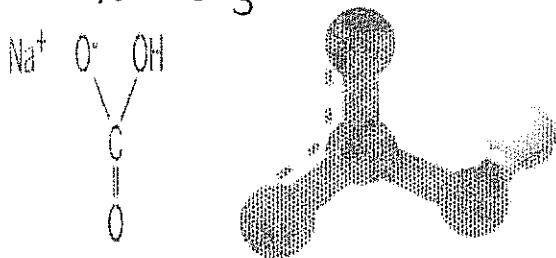

Electrolyte is

an ionic substance dissolved in H₂O

Ionic Compounds are represented by formula units. ↗ (lowest ratio of cations to anion in comp.)

ex. $CaCl_2$
 $NaCl$

Sodium Bicarbonate Ionic Compound.

Physical Properties of Ionic & Covalent Compounds

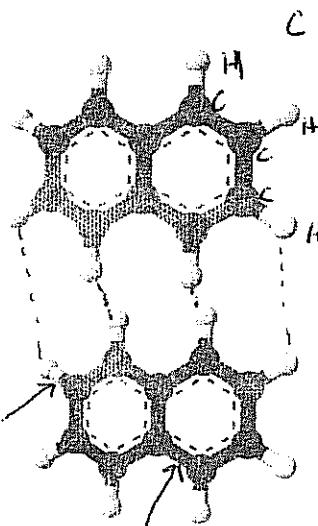

Covalent Compound

Nonpolar

$$C - H \\ 2.56 - 2.20 = .36$$

* Not Soluble in water. (no charge) Covalent bond

Covalent compounds are molecules.

They have a distinct shape & amount of atoms.

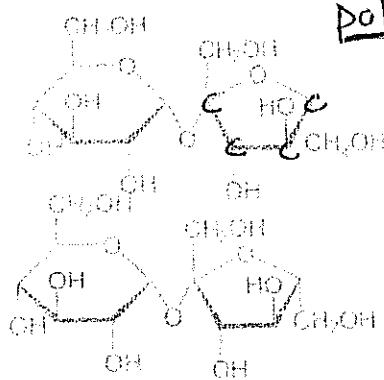

← Solid covalent compounds are held together by bonds between molecules.

- During melting these weaker bonds between molecules break.

= ↓ low melting pt.
= ↓ low boiling pt.

Sucrose Covalent Compound

Polar

$$O \quad C \\ 3.37 - 2.56 = .81$$

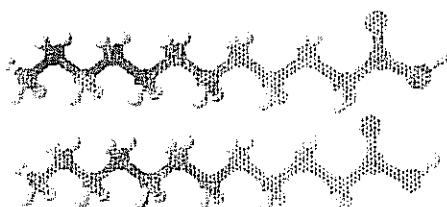

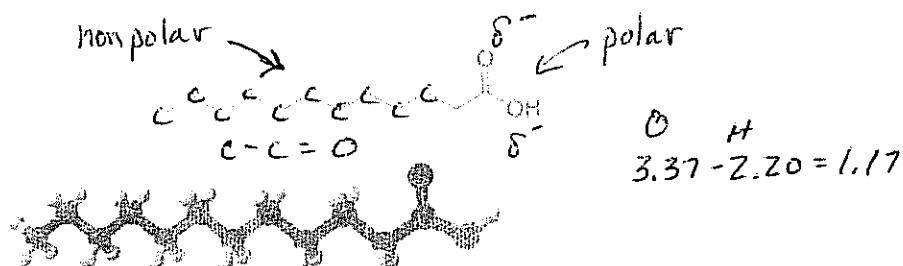

$$O \quad H \\ 3.37 - 2.20 = 1.17$$

* Soluble in water

"like dissolves like"
polar dissolves polar & ionic
(anything charged)

Lauric Acid Covalent

nonpolar

Vocabulary: Polar Covalent Bonds, Nonpolar Covalent Bonds, Ionic Bonding, Electrolyte, Electronegativity, Melting point, Solubility, Electronegativity difference (chart p. 265), Conductivity, "like dissolves like"
